WINTER LAWN CARE INFORMATION

Follow these tips to increase your lawn's appearance for the spring.

Remove Remaining Leaves

On a well manicured lawn, leaf free, a healthy layer of snow will be harmless. If you still have leaves, clean them up before the first heavy snowfall. Leaves left under the snow will disintegrate into a soupy mess holding in moisture which can cause heavy damage to your lawn.

Have Your Grass Cut Properly

You should not cut your grass too short for the winter. This can cause frost damage to your turf. However, don't leave your grass too long either. Grass can become diseased and can even smother itself if left too long for the winter.

Be Aware of Traffic

Dormant grass can tolerate a moderate amount of traffic, even under snow cover. Heavy traffic over your lawn can cause compaction and lead to a slower green up in the spring. To avoid this, clear snow from pathways and avoid compacting snow on your grass.

Put the Lawn to Bed

Winters can often be unpredictable and may put your lawn through some extreme conditions. The best thing to do is to consider these suggestions. After that, just focus on having fun in the snow!

Please call our knowledgeable staff if you would like more information

Is your lawn prepared for the winter?

The weather has cooled down and the mowers have been put away for the winter. You may be prepared to bundle up and sit by the fireplace with a warm hot chocolate, but has your lawn been bundled up for the winter? Check out the information on the left to be sure you have a great lawn when the spring comes around. Below are also some lawn care applications to consider for the early spring.

Replenish Nutrients for Spring Growth: Tree & Shrub Deep Root Feeding

Build healthier, more beautiful trees and shrubs with our seasonally timed pressure injected deep root fertilizer. Our scheduled feeding will stimulate growth, improve leaf size and thickness, enhance color and aid in root development.

Lime

It's often necessary to make applications of limestone to raise the soil's pH levels into a desirable range. Rainfall and applications of fertilizer tend to lower your lawn's pH. Schedule a lime application in the early spring to bring your pH back up and to increase your lawn's health.

Seeding

If you are planning a seeding in the spring, let us know early. A pre-emergent is the first application of the season, usually in March after the last snow melts away. This application prevents crabgrass from germinating during the season but will also inhibit the germination of desirable grass seed until the fall. We can instead schedule a fertilizer application for your lawn.
